Your agent just decided to pay a $4,000 invoice.

Six things happen before a dollar moves. For builders, operators and founders shipping agents that touch money.

1. The key only opens one drawer.

Scoped API keys. The agent that pays vendors cannot see payroll, let alone touch it. Revoke it in one call.

```
scope: ["accounts:vendors", "transfer:write"]
```

2. The limit lives on the server, not in the prompt.

A spend cap the model cannot argue with. A prompt injection can convince the agent. It cannot convince the ledger.

```
limit: { per_transfer: 5000, per_day: 12000 }
```

3. Big moves wait for a human.

Above a threshold you set, the transfer pauses and pings an owner. Unapproved requests expire. Nothing hangs forever.

```
approval: { above: 2500, expires_h: 72 }
```

4. Every move writes its own receipt.

Session id, timestamp, the reason the agent gave. An audit trail your compliance lead can read without you in the room.

```
audit: { session, ts, reason, actor: "agent:ap-01" }
```

5. Break it in simulation first.

Run the whole flow with test money. Make the agent misbehave on purpose. Watch the limits hold. Then go live.

> Builders trust a tool after they have watched it fail safely, not after it has worked once.

Your agent is the brain. It still needs safe hands.

Sequence is the execution layer: FDIC insured accounts, scoped keys, server side limits, approvals, audit. One API call.
